

1, Explain behaviour of hub device

* The hub is not intelligence device. The Hub when receive data and then it send all over the ports. So we will get collision, data loss, slow system. So Hub is a broadcast device. Layer 1 device.

2, Explain behaviour of switch device

* Switch is an intelligence device. A switch when receive a data it is first learning mac address in the mac table. then there is destination mac find it. The switch send the data to particular destination port. The mac table do not find the destination mac address then switch broadcast the data in all ports. So switch can make collision domain. It layer 2 device.

3, Explain behaviour of router device

* Router is layer 3 device. Because it is used with ip address. It use for send the packet one network to another network. One Router when receives a packet then it first check itself routing table, then send packet to correct destination ip address port. So we must configure the Router device, Next we send and receive frame one network to another network. It is host to host send the data.
